

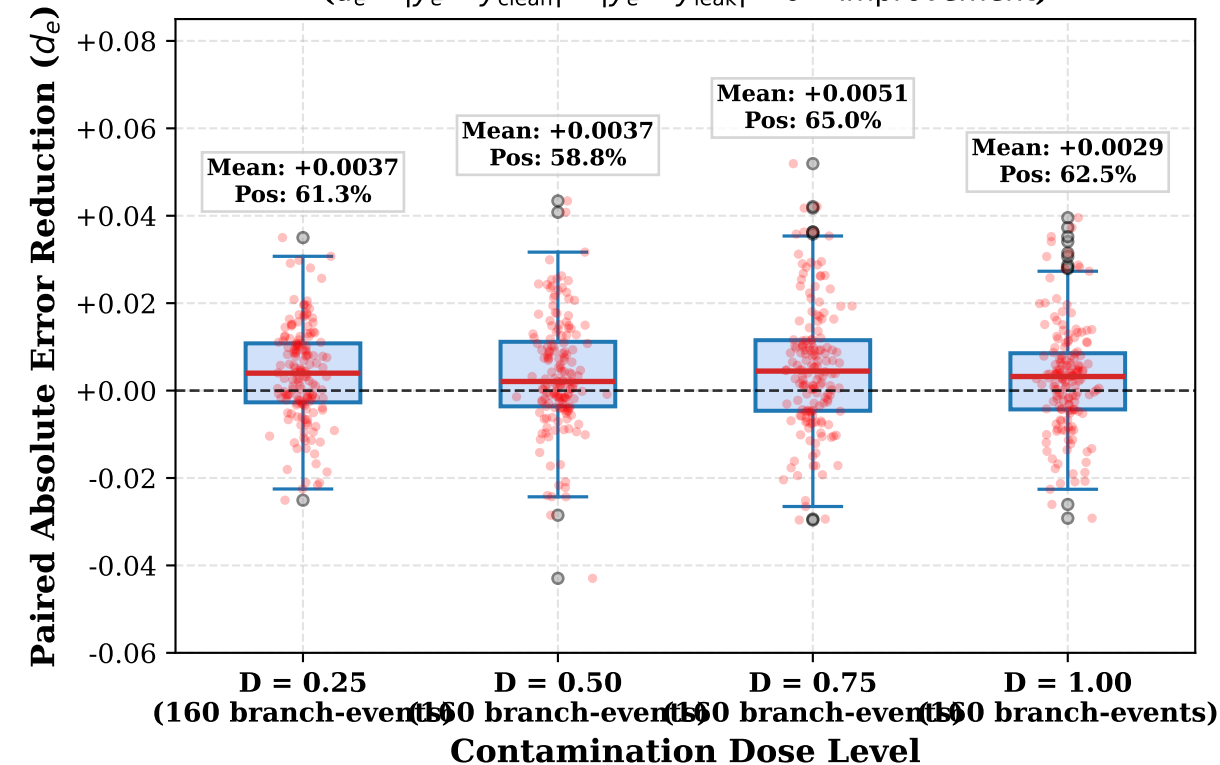

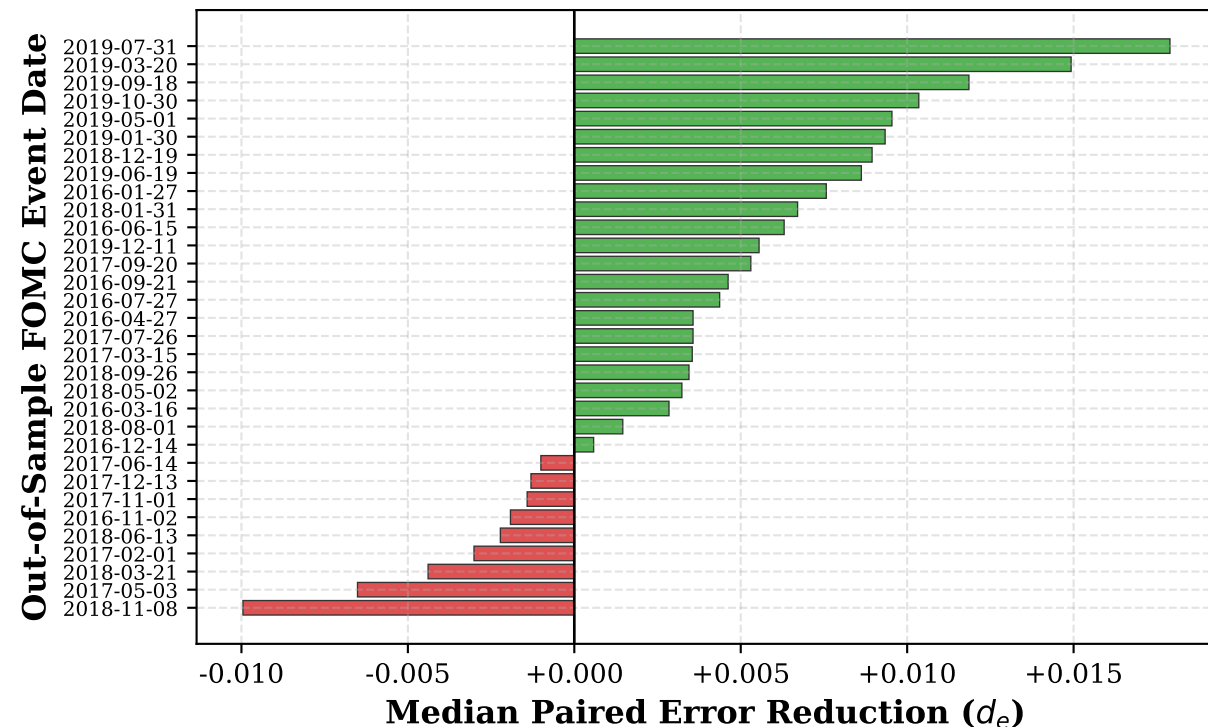

Figure 3: Distribution and Heterogeneity of Out-of-Sample Event-Level Effects (Post-Hoc Descriptive)

(A) Event Error Reductions by Contamination Dose

$(d_e = |y_e - \hat{y}_{\text{clean}}| - |y_e - \hat{y}_{\text{leak}}| > 0 \rightarrow \text{Improvement})$

(B) Event Heterogeneity Across 32 OOS Meetings
(Post-Hoc Breadth Check: 23 / 32 Meetings Show Median $d_e > 0$)

Each dose panel contains 160 branch-event observations (32 OOS events x 5 seeds). These observations are not independent and are displayed for post-hoc descriptive visualization only. The preregistered inferential unit remains the independent FOMC event. Breadth check illustrates that gains were not concentrated in an isolated meeting.
